## 1.2 Identification

The specification document establishes the design requirements for the tracking system.

## 1.3 System Overview

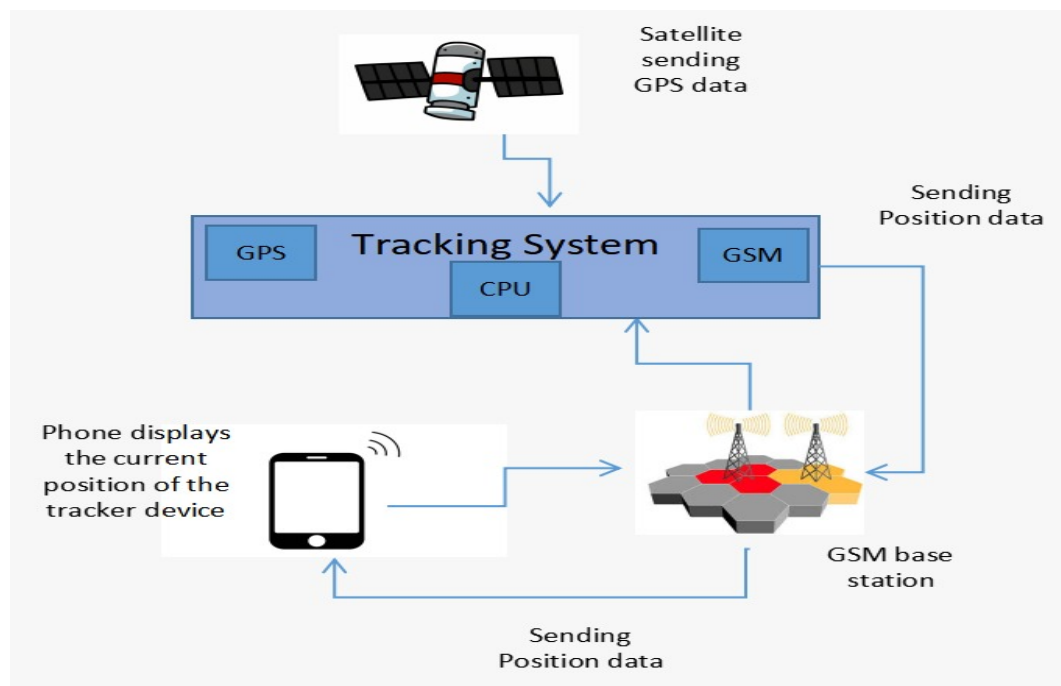

Figure 1: *System block diagram*

A tracking system consists of GPS and GSM modules to trace the current position of the vehicle on which the tracking system is mounted. The GUI (Graphical User Interface) is provided in the mobile phone for the user to initiate the tracking. The server is used to do the tracking calculation. The processor is used to read and transfer the position data to the server through GSM. Finally the mobile application conveys the position in the map.

## **1.4 Document Overview**

This Specification document establishes the specification for the Tracking System. The document follows the format and the guidelines formulated by the professor.Dr.Ing.Andreas Siggelkow.

## 2 Requirements

| Requirement  | ID    | Importance | Verification   | Description   |
|--|-------|------------|--|---|
| <b>General</b>   |       |            |  |   |
| Gen.: GPS  | G01   | HIGH       | The GPS data format is generated and transmitted to processor in SystemC test bench. | The GPS reads the current position of the device from the satellite in the form of NMEA format.                                       |
| Gen.: GSM  | G02   | HIGH       | SystemC test bench   | One GSM module is used to initiate the tracking event from the server and to receive the position data at the server from the device. |
| <b>Memory</b>  |       |            |  |   |
| Memory : Write GPS data to on board memory 1                 | Mem01 | HIGH       | SystemC Test bench   | The processor has to write the last updated position data (approx.1 to 2m accuracy )to the on board memory.                           |
| Memory : Write GSM base station network position to memory 2 | Mem02 | HIGH       | SystemC Test bench   | The processor has to write the last updated network base station position (100 to 200 m accuracy)to the on board memory.              |

|                      |        |      |                      |   |
|----------------------|--------|------|----------------------|---|
| <b>UART 1</b>        | UART01 |      | Tested using<br>FIFO |   |
| UART 1: 115200       |        | HIGH | SystemC Test bench   | The speed of the serial transmission should be set to 115200 baud               |
| UART 1: 8 bit        |        | HIGH | SystemC Test bench   | The data width of the serial transmission should be set to 8 bit.               |
| UART 1: no parity    |        | HIGH | SystemC Test bench   | The serial transmission should not be verified with a parity bit.               |
| UART 1: one stop bit |        | HIGH | SystemC Test bench   | The serial transmission should end with the one end point.                      |
| UART 1: GPS Data     |        | HIGH | SystemC Test bench   | The GPS data has to be read by the processor from the GPS module through UART1. |
| <b>UART 2</b>        | UART02 |      | Tested using<br>FIFO |   |
| UART 2: 115200       |        | HIGH | SystemC Test bench   | The speed of the serial transmission should be set to 115200 baud               |
| UART 2: 8 bit        |        | HIGH | SystemC Test bench   | The data width of the serial transmission should be set to 8 bit.               |

|                      |  |      |                    |   |
|----------------------|--|------|--------------------|---|
| UART 2: no parity    |  | HIGH | SystemC Test bench | The serial transmission should not be verified with a parity bit. |
| UART 2: one stop bit |  | HIGH | SystemC Test bench | The serial transmission should end with the one end point.        |
| UART 2: GPS Data     |  | HIGH | SystemC Test bench | UART2 is used by the GSM to send and receive data between MCU     |

### 3 Product Top level

The SystemC is the programming language which is used to design and the test the tracker system. There are totally five modules used to design the system and those are :

1. GPS : This module continuously sends the predefined GPS data to the processor through the FIFO1 (acts as UART1).
2. GSM : This module has two operation, one is to send the tracker system network base station data to the processor and other one is to send the track event(it is considered as a character X) to the processor (through FIFO 2 acts as a UART 2) which is generated by the phone and to receive the location data from the processor through FIFO 3 (acts as a UART 2).
3. Bus : This module just forms the data transmission bridge between master and slave. The data transmission is character by character (using TLM module).
4. Micro controller : This module is the main controlling unit of the system which receives the location data from the GPS and GSM and stores it in the memory. And wait for the wake up call (character X) from the phone via GSM. Once the character is received the processor read location data from memory and sends back to phone via GSM.
5. Memory : This module stores the GPS and GSM data at particular memory location. Whenever there is a read back request from the processor memory sends back the stored data to the processor.

The Figure 2 shows the top level of the chip with systemC implementation ideas:

The MCU continuously receives data from the GPS or GSM and writes to respective on board memory. Suppose there is an event from GSM for the track location(event X), the MCU reads the location data from memory and send back to the phone via GSM.

## IO Details

| Pin      | Direction | Width                | Explanation   |
|----------|-----------|----------------------|---|
| Clk_i    | in        | 1                    | System clock  |
| Rst_i    | in        | 1                    | System reset, active low  |
| Gps_i    | in        |                      | Air interface to the satellites, represented by a FIFO for chars or unsigned int (template)   |
| Gsm_i    | In        |                      | Air interface from the GSM network, represented by a simple bus interface (SystemC / TLM)   |
| Gsm_o    | Out       |                      | Air interface to the GSM network, represented by a simple bus interface (SystemC / TLM)   |
| Bus<1,2> |           | char or unsigned int | The bus has two contributors: <ul style="list-style-type: none"> <li>• Master: the MCU</li> <li>• Slave: memory 1, for GPS data</li> <li>• Slave: memory 2, for GSM data</li> </ul> |

## 4 Architecture Concept

The task is to design the simple bus and master MCU which connects the different slave modules and is responsible for the data transmission between the connected modules. The Simple bus and the master uses the various sockets and interfaces, the figure 4 shows how the master is interfaced between the different slaves, similarly how the bus acts as a bridge between the master and the memory.

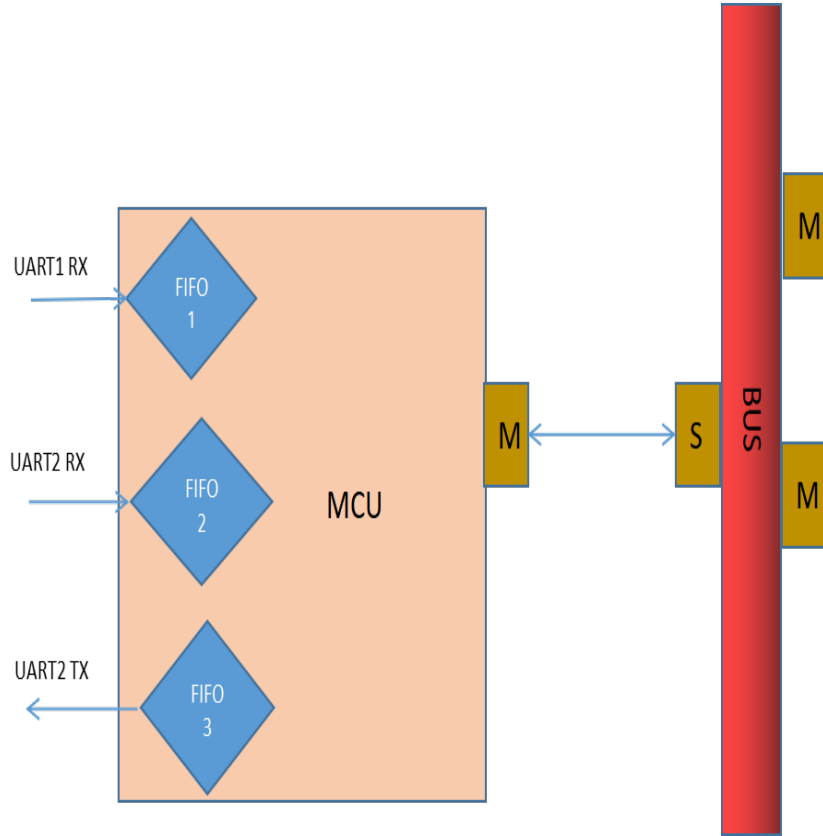

Figure 4: *MCU-Bus top level*

MCU use one master socket to communicate with the bus, where the bus use slave socket for the communication. MCU communicates with the GSM and GPS by the mean of FIFO (which acts as UART) which is a interface between MCU and both GPS and GSM. Bus uses two master socket in the other side to communicate with the two memories. In order to test the primary module ( Master + Bus), the sub modules GPS, GSM and memory are used which are considered as a test bench for the primary module.

The sub-module interface are :

1. GPS and GSM connects with Master
2. Bus connects with two memories

#### 4.1 Master and Bus

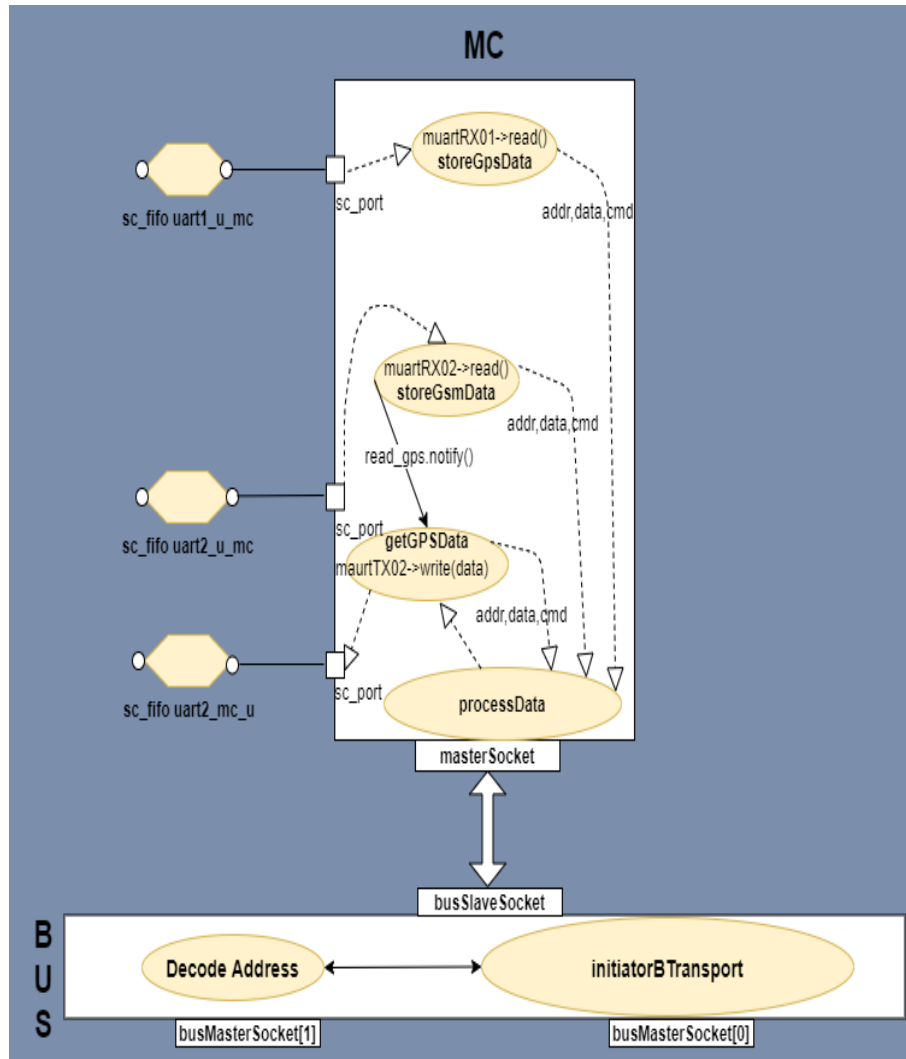

Figure 5: *Architecture of Master and bus*

The figure 5 show the complete architecture between the master and the bus, how the sockets and fifo's are incorporated in the primary module.

#### 4.1.1 Bus

The Simple bus is a communication link between master and memory. Sockets and functions are used in bus which are shown in figure 5 and the explanations are given below.

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Bus  |
| <b>Type</b>                 | Socket   |
| <b>Name</b>                 | busSlaveSocket   |
| <b>Specification number</b> | SPEC01   |
| <b>Description</b>          | Socket acts as slave socket in bus and the socket is connected to socket in master |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Bus  |
| <b>Type</b>                 | Socket   |
| <b>Name</b>                 | busMasterSocket[0]   |
| <b>Specification number</b> | SPEC02   |
| <b>Description</b>          | Socket acts as master socket in bus and the socket is connected to slave 1 socket. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Bus  |
| <b>Type</b>                 | Socket   |
| <b>Name</b>                 | busMasterSocket[1]   |
| <b>Specification number</b> | SPEC03   |
| <b>Description</b>          | Socket acts as master socket in bus and the socket is connected to slave 2 socket. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Bus  |
| <b>Type</b>                 | Function   |
| <b>Name</b>                 | void decode_address(const uint64 address, uint64& masked_address)  |
| <b>Specification number</b> | SPEC05   |
| <b>Description</b>          | In this function port ID of the slave is determined from the upper 4 bytes[31-28] from 32-bit address and the address is determined from the lower 28 bytes[27-0]. |

|                             |   |
|-----------------------------|---|
| <b>Module</b>               | Bus   |
| <b>Type</b>                 | Function  |
| <b>Name</b>                 | void initiatorBTransport(int SocketId, payLoad_t& trans, sc_time& t)  |
| <b>Specification number</b> | SPEC04  |
| <b>Description</b>          | The function initiatorBTransport is registered as callback method to the slave socket. This will establish the communication link between the master CPU and memories. The first step in this function to get port ID of the slave and the address of the slave from the masked address which sent from the master CPU. Second step to send the data and address to the respective slave. |

#### 4.1.2 MCU

Master is responsible for read and write operation. When Master receives GPS and GSM data through port from respective module, master write the corresponding data to respective memory. If master receives a request to read GPS data from slave, it will read the data from the slave and forward data to GSM module through port. Usage of ports, sockets and functions as shown in figure 5 are explained below.

|                             |   |
|-----------------------------|---|
| <b>Module</b>               | Master  |
| <b>Type</b>                 | Port  |
| <b>Name</b>                 | muartRX01(template : unsigned char or int)  |
| <b>Specification number</b> | SPEC06  |
| <b>Description</b>          | Port muartRX01 initialized as sc_fifo_in_if, which receives the GPS data from GPS module. |

|                             |   |
|-----------------------------|---|
| <b>Module</b>               | Master  |
| <b>Type</b>                 | Port  |
| <b>Name</b>                 | muartRX02(template : unsigned char or int)  |
| <b>Specification number</b> | SPEC07  |
| <b>Description</b>          | Port muartRX02 initialized as sc_fifo_in_if, which receives the GSM data from GSM module. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Master   |
| <b>Type</b>                 | Port   |
| <b>Name</b>                 | muartTX02(template : unsigned char or int)   |
| <b>Specification number</b> | SPEC08   |
| <b>Description</b>          | Port muartTX02 initialized as sc_fifo_out_if, which send the GPS data to GSM module. |

|                             |   |
|-----------------------------|---|
| <b>Module</b>               | Master  |
| <b>Type</b>                 | Socket  |
| <b>Name</b>                 | masterSocket  |
| <b>Specification number</b> | SPEC09  |
| <b>Description</b>          | The masterSocket is initiator socket, which is connected to the bus slave socket. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Master   |
| <b>Type</b>                 | Event  |
| <b>Name</b>                 | read_gps   |
| <b>Specification number</b> | SPEC10   |
| <b>Description</b>          | The event read_gps is triggered when the character 'x' is received from GSM module in function storeGSMDData(). When event is triggered the GPS data read from the memory 1 and sent to GSM module through fifo in getGPSData(). |

|                             |   |
|-----------------------------|---|
| <b>Module</b>               | Master  |
| <b>Type</b>                 | Function  |
| <b>Name</b>                 | void processData(uint32_t address, char* data, int cmd)   |
| <b>Specification number</b> | SPEC11  |
| <b>Description</b>          | Function receives the address, data and command as an input parameters. In this function generic payload is filled and sent through the socket b_transport. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Master   |
| <b>Type</b>                 | Thread   |
| <b>Name</b>                 | void storeGPSData(void)  |
| <b>Specification number</b> | SPEC12   |
| <b>Description</b>          | The storeGPSData() is registered as a SC_THREAD in the constructor. The data is read from the port muartRX01 and forwarded to memory1. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Master   |
| <b>Type</b>                 | Thread   |
| <b>Name</b>                 | void storeGSMDData(void)   |
| <b>Specification number</b> | SPEC13   |
| <b>Description</b>          | The storeGSMDData() is registered as a SC_THREAD in the constructor. The data is read from the port muartRX02 and sent to memory2 if character 'x' is not received. If 'x' is received, notify the read_gps event. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Master   |
| <b>Type</b>                 | Thread   |
| <b>Name</b>                 | void getGPSData(void)  |
| <b>Specification number</b> | SPEC14   |
| <b>Description</b>          | The getGPSData() is registered as a SC_THREAD in the constructor. The thread will wait until the read_gps event is occur. Once event is notified, read GPS data from the memory 1 and sent to GSM module through port. |

## 4.2 Testing primary module

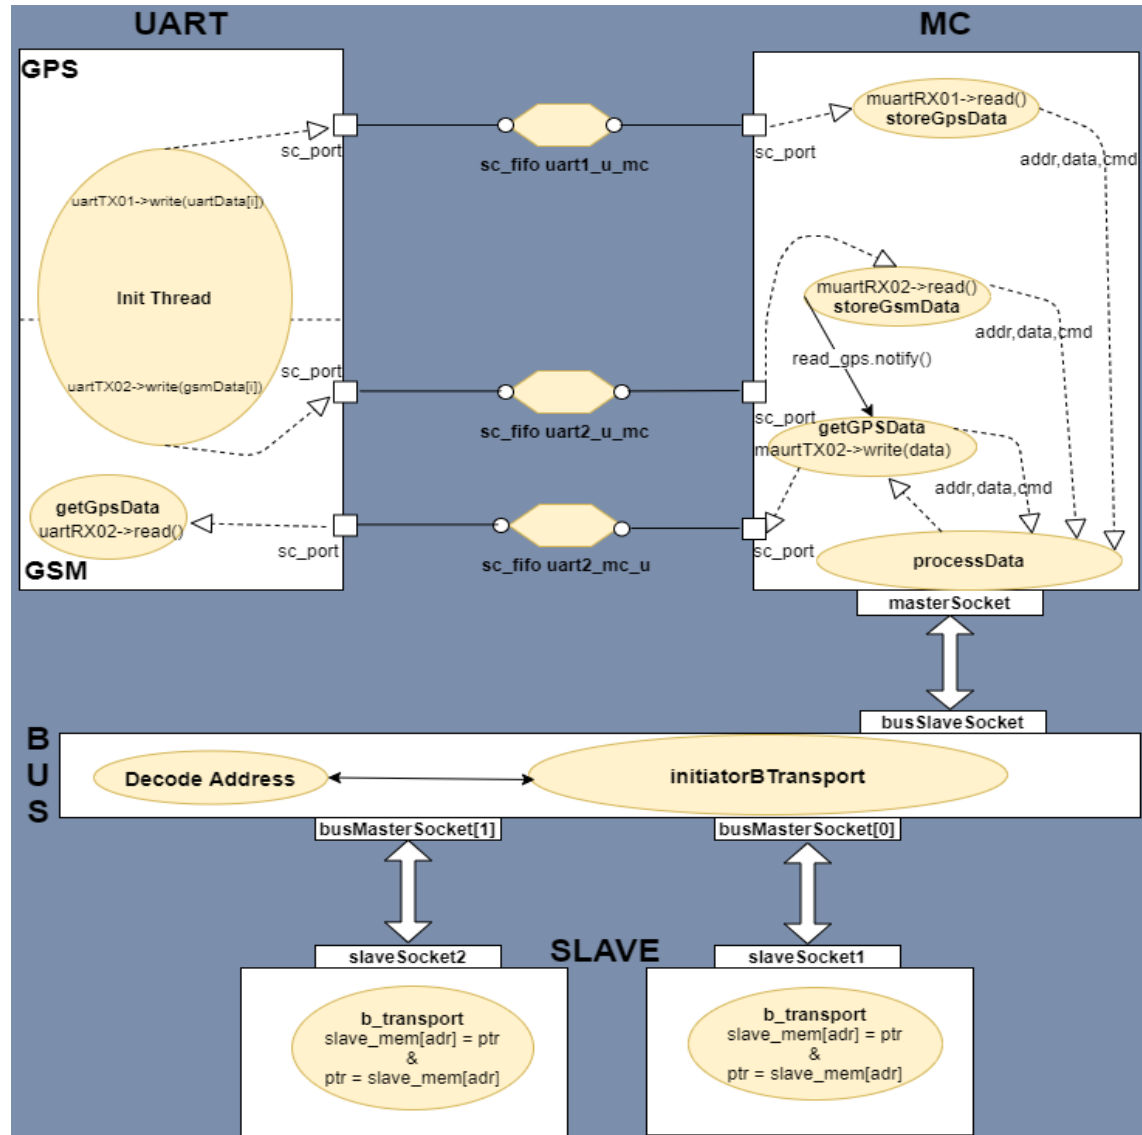

Figure 6: Architecture of complete primary and sub-module

### 4.2.1 UART

UART module is a testing module where GPS and GSM data are predefined and sent to master through port and GSM receives the GPS data through port from Master. The explanation for the sockets and the functions which are shown in figure 6 are given below.

|                             |   |
|-----------------------------|---|
| <b>Module</b>               | UART  |
| <b>Type</b>                 | Port  |
| <b>Name</b>                 | uartTX01(template : unsigned int or char)   |
| <b>Specification number</b> | SPEC15  |
| <b>Description</b>          | Port uartTX01 initialized as sc_fifo_out_if in GPS module, which sends the GPS data from GPS module to MCU. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | UART   |
| <b>Type</b>                 | Port   |
| <b>Name</b>                 | : uartTX02(template : unsigned int or char)  |
| <b>Specification number</b> | SPEC16   |
| <b>Description</b>          | Port uartTX02 initialized as sc_fifo_out_if in GSM module, which sends the GSM data from GSM module to master CPU. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | UART   |
| <b>Type</b>                 | Port   |
| <b>Name</b>                 | uartRX02(template : unsigned int or char)  |
| <b>Specification number</b> | SPEC17   |
| <b>Description</b>          | Port uartRX02 initialized as sc_fifo_in_if in GSM module, which receive the GSM data from MCU. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | UART   |
| <b>Type</b>                 | Thread   |
| <b>Name</b>                 | initUart(void)   |
| <b>Specification number</b> | SPEC18   |
| <b>Description</b>          | Thread initUart is used to send the GPS and GSM data to master. This is a test function. |

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | UART   |
| <b>Type</b>                 | Thread   |
| <b>Name</b>                 | getGpsData_f(void)   |
| <b>Specification number</b> | SPEC19   |
| <b>Description</b>          | The getGpsData_f() is registered as a SC_THREAD in the constructor. Here gps data is received from master and printed on terminal. |

#### 4.2.2 Memory

Memory is consider to be a slave, in write operation it stores the data and in the read operation copies the data back to payload. The explanation for the sockets and the functions which are shown in figure 6 are given below.

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Memory   |
| <b>Type</b>                 | Socket   |
| <b>Name</b>                 | slaveSocket  |
| <b>Specification number</b> | SPEC20   |
| <b>Description</b>          | Slave socket is target socket, where it is connected to the target socket in the master CPU. |

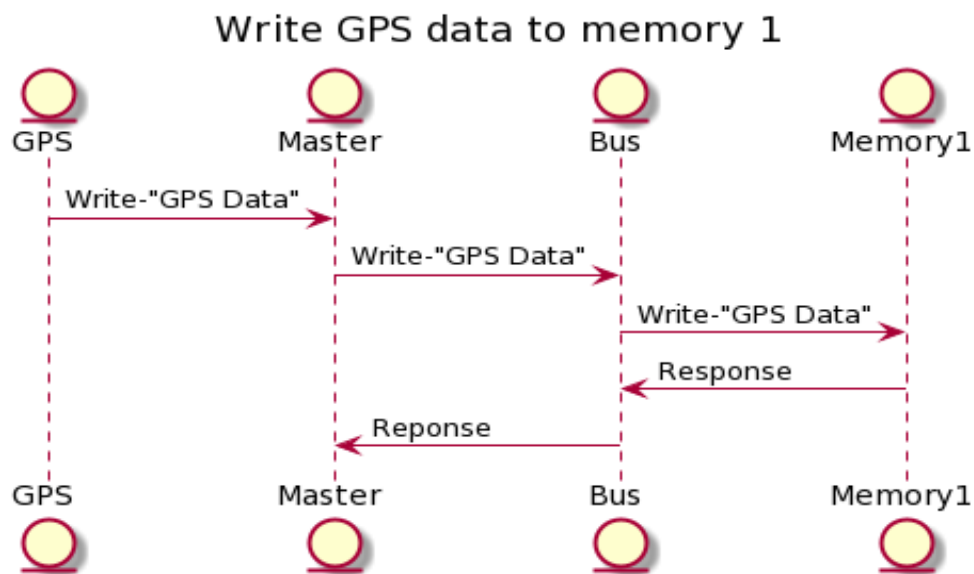

|                             |  |
|-----------------------------|--|
| <b>Module</b>               | Memory   |
| <b>Type</b>                 | Function   |
| <b>Name</b>                 | b_transport(tlm::tlm_generic_payload &trans, sc_time &delay)   |
| <b>Specification number</b> | SPEC21   |
| <b>Description</b>          | The function b_transport is registered as callback method to the slave socket. In this function the read or write command is checked. If command is received as read, the data is copied from memory to payload or vice-versa. |

## 5 Data Flow

Data read or write to memory from GPS and GSM modules happens in 3 ways and they listed below.

1. Write GPS data to memory 1
2. Write GSM data to memory 2
3. Read GPS data from memory 1.

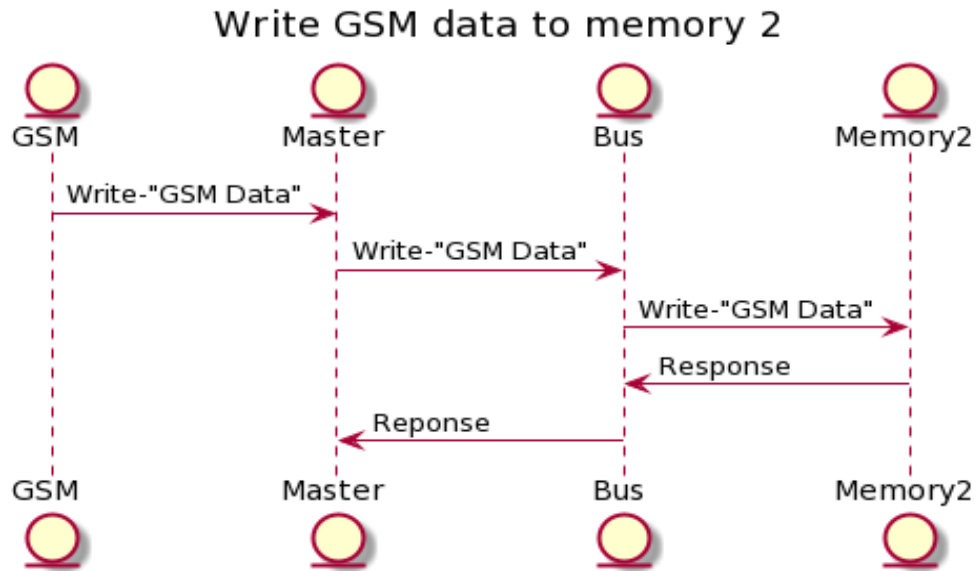

### 5.1 Write GPS data to memory 1

Steps followed :

1. Master continuously reads the GPS data from the GPS module.
2. Master writes the received GPS data to the BUS.
3. BUS write the GPS data to the particular address in the memory 1.

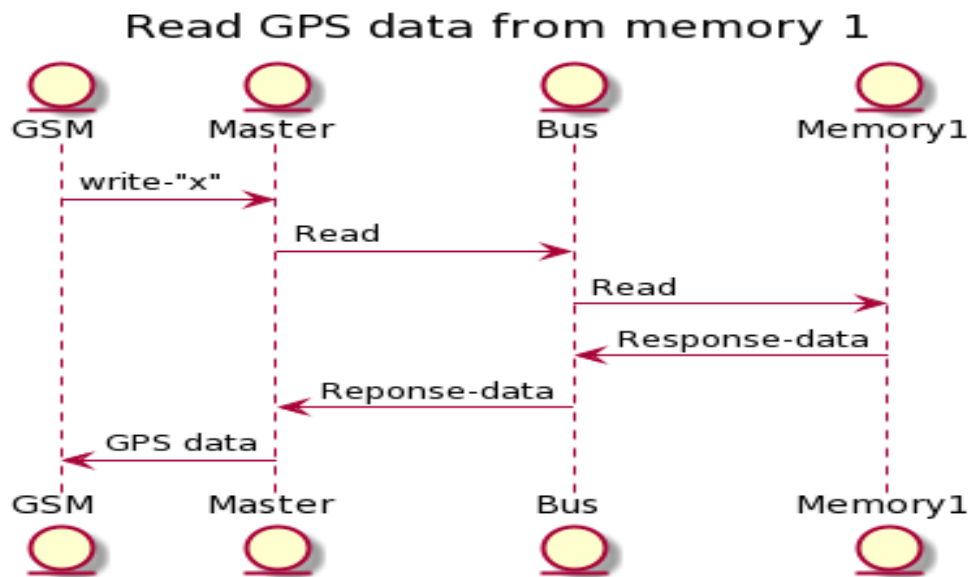

## 5.2 Write GSM data to memory 2

Steps followed :

- 1.Master continuously reads the GSM data from the GSM module.
- 2.Master writes the received GSM data to the bus.
- 3.BUS writes the GSM data to the particular address of the memory 2.

### 5.3 Read GPS data from memory 1

Steps followed :

- 1.If master receives the track request from the phone via GSM, it sends the data read request to the memory via bus.
- 2.When memory1 receives the read request from the master, it sends back the stored data to master.
3. when the Master receives the data from the memory, it send the same data to the server via GSM.

## 6 Requirement and specification traceability

| Requirement ID number | Specification number                |
|-----------------------|-------------------------------------|
| G01                   | [SPEC18]                            |
| G02                   | [SPEC18]                            |
| Mem01                 | [SPEC09] [SPEC01] [SPEC02] [SPEC20] |
| Mem02                 | [SPEC09] [SPEC01] [SPEC03] [SPEC20] |
| UART01                | [SPEC15] [SPEC06]                   |
| UART02                | [SPEC16] [SPEC07]                   |
| UART02                | [SPEC08] [SPEC17]                   |
| Bus01                 | [SPEC09] [SPEC01] [SPEC02] [SPEC03] |
